## Summary

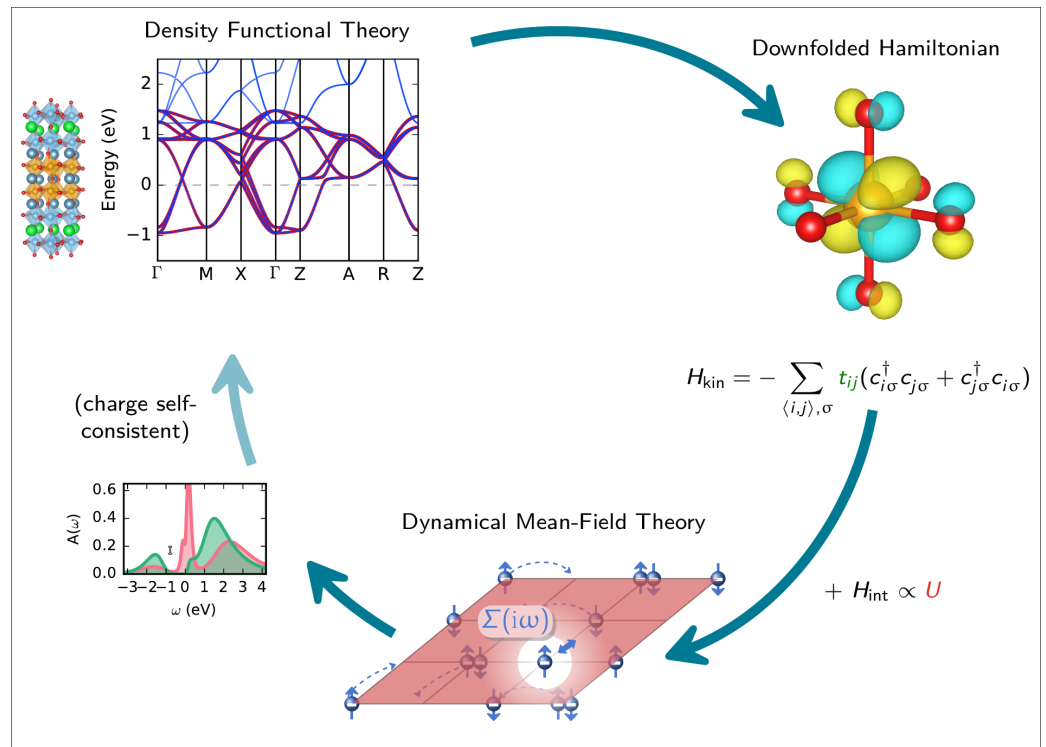

Strongly correlated systems are a class of materials whose electronic structure is heavily influenced by the effect of electron-electron interactions. In these systems, an effective single-particle description may not capture the many-body effects accurately. Although density functional theory (DFT) plus dynamical mean-field theory (DMFT) has proven successful in describing strongly correlated electron systems for over two decades, it has only been very recently that ready-to-use software packages began to become available, with most scientific research carried out by self-written codes developed and used in research groups. Given the complexity of the method, there is also the question of whether users should implement the formalism themselves for each problem or whether ready-to-use black-box software, as is the case with many DFT software packages, is beneficial to the community.

The goal of solid\_dmft is to find a middle ground, i.e., a *gray-box* tool as a ready-to-use implementation. This means that while the code contains all the functionality needed for many standard DMFT calculations, it is highly modular, based on open-source and community-developed software, and therefore can be easily adapted to specific applications and needs. Hence, this project is targeted towards researchers aiming to apply DMFT methods on top of DFT simulations to describe the physics of strongly correlated electron systems. While our approach allows one to fully perform these computations using standardized input flags without further need for elaborate coding, the final user can easily extend the functionalities by modifying the corresponding modules in the code.

The package is MPI-parallelized and written in Python 3, utilizing the publicly available TRIQS software library ([Parcollet et al., 2015](#)) and its available applications. The philosophy of the package is to increase reproducibility of DFT+DMFT calculations, provide clearer convergence metrics, and allow to run calculations for a large variety of systems without adapting the code manually, i.e., on a level similar to widely available DFT simulation packages.

## Design Principles

solid\_dmft uses the state-of-the-art implementations provided by the TRIQS library and its applications. This allows to easily run ab-initio calculations for strongly correlated materials, as well as implement and test new features of TRIQS and benchmark new solvers against existing ones. solid\_dmft manages the calls of the necessary routines to run the DFT calculations, create the downfolded Hamiltonian, solve the resulting Hubbard-like Hamiltonian via DMFT, postprocess the data to calculate physical observables, and allow for charge-corrected feedback via charge self-consistency. The full DFT+DMFT cycle is presented in [Figure 1](#).

**Figure 1:** Fully charge self-consistent DFT+DMFT cycle. Starting from a DFT calculation (top left), a downfolded Hamiltonian and projector functions are created via optimized projections on a local basis set (top right). By adding a specified interaction Hamiltonian  $H_{\text{int}}$ , a full interacting electron problem is created, to be solved via the DMFT equations in TRIQS (bottom). After convergence in DMFT is reached, physical observables are calculated (bottom left). For fully charge self-consistent calculations, the DFT cycle is restarted with a DMFT-corrected charge density.

41 The code is designed to run on top of a DFT calculation or a tight-binding model, which  
 42 provide the low-energy (downfolded) description of a periodic system. The DFT calculations  
 43 can be performed with any code that is compatible with TRIQS/DFTTools (Aichhorn et  
 44 al., 2016). The input for the DMFT calculation can be provided either as a Hamiltonian in  
 45 reciprocal  $\mathbf{k}$ -space in a localized basis set or in terms of the overlap between the localized  
 46 basis set and the Kohn-Sham wavefunctions (so-called projector functions) and their respective  
 47 eigenvalues. The DFT output is converted by TRIQS/DFTTools into an HDF5 archive in a  
 48 standardized structure to be used by solid\_dmft.

49 The code follows the same modular philosophy as the TRIQS software package, relying on  
 50 TRIQS functionalities to perform basic operations on Green functions. Each part of the  
 51 simulation is split into separate stand-alone functions to limit statefulness to a minimum and  
 52 allow for an easy extension of functionalities. The modularity of the program also allows to  
 53 run, for example, the DMFT loop via a call of a single pure function with well-defined input  
 54 and output, i.e., without running solid\_dmft as a monolithic code. An abstracted solver class  
 55 implements the various impurity solvers available in TRIQS. solid\_dmft allows to seamlessly  
 56 switch between impurity solvers with the change of a simple input flag and by adjusting  
 57 the solver parameters. A fully charge self-consistent interface is implemented for Quantum  
 58 ESPRESSO (Giannozzi et al., 2009) and the Vienna ab-initio simulation package (VASP)  
 59 (Kresse & Furthmüller, 1996; Kresse & Hafner, 1993). solid\_dmft also allows to perform  
 60 inhomogeneous DMFT calculations, i.e., the treatment of multiple correlated and uncorrelated  
 61 shells (impurity problems). Postprocessing scripts are available to perform analytic continuation  
 62 of imaginary Green functions or self-energies, and to calculate spectral functions.

63 As of now, solid\_dmft has been successfully used in various peer-reviewed research studies

(Beck et al., 2022; Hampel et al., 2019, 2020, 2021; Merkel & Ederer, 2021; Zhang et al., 2022). We provide releases matching those of the TRIQS library, as well as an updated documentation, tutorials, and a reference manual. Examples and benchmark calculations can be found in the tutorials section of the documentation. Furthermore, we utilize a continuous-integration workflow on GitHub to test every pull request and commit.

## Statement of need

As of now, only few ready-to-use DFT+DMFT codes are available, all of them released rather recently. Most of these codes adopt a black-box approach, where the complexity of the DMFT part is abstracted away from the final user (as in EDMFT (Haule et al., 2010), Amulet (Poteryaev & others, n.d.) or the DMFT implementation in Abinit (Romero et al., 2020)) and therefore reduces the number of free parameters to tune. However, this approach may limit the flexibility of the implementation. `solid_dmft` is designed as a more modular, and open source implementation, similar to other software packages like DFTwDMFT (Singh et al., 2021) and DCORE (Shinaoka et al., 2021), and provides a flagship implementation of the TRIQS functionality. The benefits of this approach are twofold: on the one hand, developers of the TRIQS ecosystem are able to benchmark their applications in a well-tested framework. On the other hand, users can benefit from a standardized input-output structure compatible with the TRIQS framework, fundamentally increasing robustness and reproducibility. `solid_dmft` is developed in the spirit of a community code and supports external contributions that advance the capabilities of the software.
